Graphical programming AutoCAD has many utilities that enable the creation and manipulation of objects in a graphical way. These can be dragged and dropped, moved or copied. They can be combined or removed, and if moved they can be relocated to a different layer or frame. The drawing canvas can be divided into specific layers to enable the user to work on different sets of information. Customization of the drawing interface is controlled through the user interface system. The options and controls for users to work with are controlled through command line and contextual menus. AutoCAD can be integrated with other applications and with other users. It can be integrated with a remote data source, and the data can be displayed in an external application. Example Applications To help customers use AutoCAD, a number of applications have been developed to either replace traditional AutoCAD features or add new functionality. This is often through interfaces which allow the user to interact with a program via a mouse or via a drawing on the screen. There is also a set of scripts which can be used to automate processes. An example of this is the development of GIS applications to take the information from a GIS and display it on the screen. In Excel, I'm trying to export a file with named ranges. These named ranges have placeholders for a large amount of data. I would like to export the file, but I only want the data that is within the named range, so I'm using named ranges that only contain data. The following code does what I want. Sub ExportFile() Dim fd As Integer Dim fdname As String Dim vfilename As String Dim inx As Integer Dim inx2 As Integer Dim fname As String Dim i As Integer a1d647c40b
