Field of the Invention This invention relates generally to the geophysical exploration of hydrocarbon bearing formations penetrated by a borehole, and more particularly to the use of downhole hydrophone technology to record downhole seismic signals (or "seismic vibrations"), as a function of time, from the fluid in the borehole. 2. Description of the Related Art In a hydrocarbon recovery operation such as oil and gas production or marine seismic surveying, it is often desirable to record acoustic signals within a borehole. The signals may be collected by the use of a downhole hydrophone. The acoustic signals are generated as a result of the vibrational energy of the borehole fluid which is caused by the drilling operation. The acoustic signals are attenuated in accordance with the distance between the borehole fluid and a collecting location. As such, the effectiveness of the collection of the acoustic signals by the use of a downhole hydrophone decreases with depth. The geometric effects on the collected signals can be modeled as a function of frequency and attenuation distance. The seismic survey of hydrocarbon bearing formations is most often accomplished by collection of the acoustic signals at a receiver towed at a distance from the bottom hole of the well. Consequently, the maximum depth of the
